

Combinatorial non-positive curvature in group theory

Damian Osajda

In *Geometric Group Theory* we study groups by means of their actions on spaces.

From geometric/topological/large scale properties of the spaces we deduce algebraic/algorithmic features of the groups.

General Problem:

Find and study local combinatorial conditions (CNPC) on a polyhedral complex implying asphericity.

Example: 1-dimensionality

Example: 2-dimensional complex with 2-cells being n -gons with $n > 5$ (small cancellation)

Higher dimensions:

- CAT(0) cubical complex
- systolic complex
- weakly modular complex
- Helly complex

Application #1:

Study „classical” groups:

- arithmetic lattices
- groups of birational transformations
- Coxeter/Artin/braid groups
- fundamental groups of complexified complements of hyperplane arrangements

Application #2:

Construct new (exotic) groups:

- high-dimensional Gromov hyperbolic groups
- groups not coarsely embeddable into the Hilbert space
